WALT: Understand the human life cycle

The Human Life Cycle

The human life cycle has 6 main stages, which are very important so I'm going to tell you about it.

The first stage ⁱⁿ the cycle is the ^{stage} foetus which is where it's in the mother's womb. It can only be classed as a foetus after 8 weeks. Sadly, some women can lose their baby before or after birth. It would take 9 months for the baby to develop and come into the world. The second stage, is where they are a baby, a tiny baby and need their mothers a lot! They need their mothers for feeding, tracking, changing and more. This stage should last till their 2. Next, is the child stage where they are between the ages 3 and 12. At this point, they can go to school and get an education. They still need their parents, but not as much. The next stage, is the Adolescent (teen), you can have mood swings and hit puberty. They are a teen between 13 and 17. Even though they are older, they still need their parents. Between these stages they can learn to drive. The second to last stage is the adult stage, where they have no help from their parents at all! This is ~~a~~ in between the age of 18 and 66. In this stage they can start a family of their own and work to provide for the family. They also have to help their own children and elderly family. The final stage is the elderly stage, they shrink and get wrinkly! They are usually 67 and up and need help from their children and grandchildren. Some may get ~~chronic~~ diseases such as dementia and Alzheimer's.

That is our life cycle! Live long and live. Enjoy life!

LO ✓ Very detailed, excellent Amy. Can you describe the pattern of dependency from childhood to adulthood?
Needs parents Needs parents doesn't need parents. ✓✓

Amy
